

Multimoded RF Systems for Future Linear Colliders

Sami G. Tantawi

Acknowledgment

This work is a result of a continuous effort by many researches and engineers over many years.

In particular, The efforts of C. Nantista, N. Kroll, R. Miller, P. Wilson, V. Dolgashev, K. Fant, C. Pearson, R. Ruth, were instrumental to the results achieved to date.

Jose Chan: A persistence efforts during the manufacturing and testing of components

David Schultz Denis Atkinson, C. Adolphsen D. Burke and the NLC group

J. Nelson, K. Jobe, M. Ross, J. Frisch, T. Smith, D. McCormick, and the NLCTA operations team were a must for the successful conclusion of this project.

D. Cassel, J. DeLamare, M. Nguyen, M. Laruss and the modulator team

K. Ratcliffe and the Vacuum Assembly Team.

We wish to Thank all operators that took shifts 24 hours a day for several months

Outline

- Dualmode resonant delay line pulse compression system for the Next Linear Collider (NLC)
 1. Introduction
 2. Components: design and cold tests
 3. Dualmode Delay Lines: Design and Experimental results
 4. High power experimental results

RF Accelerator Structures needs a short, high power, rf pulse. For example the current NLC design requires a flat-top 396 ns rf pulse with a power level of about 95 MW/m at 11.424 GHz, and a repetition rate of 120 Hz to feed each accelerator structure.

One need to transfer the CW wall plug power to rf pulses with high power and low duty factor. Hence

1. A storage system is needed.
2. A Switch or a switching mechanism is needed to control the charging and discharging of the system.
3. A device to generate the RF power

Storage Systems:

1. Capacitors; i.e. Modulators.

Switches include pulse forming networks, thyrotrons, IGBTs, and grided guns on microwave tubes.

2. Kinetic energy of an electron beam ; i.e. two beam accelerator,

Switches include RF beam kickers

3. In the accelerator structure; i.e. super conducting accelerators.

4. *In rf transmission lines and cavities; i.e. rf pulse compression systems.*

Switches includes rf phase manipulation between rf sources, and solid state switches.

In general most of rf systems, suggested for a linear collider, contains elements from several of the above storage system.

To compare these system one has to consider:

1- Philosophy of the design

- Modularity: one may choose to have a unit that contains one rf source, and compact pulse compression system such as SLED-II
- Flexibility in the operating rf frequency: one may choose Two beam systems
-

2- Efficiency

3- Cost

The choice of the system is greatly affected by the available technology of the components.

If one has

1- A really inexpensive efficient rf source

2- A a very efficient and inexpensive modulator system using a very fast switch (such as grided gun on the rf source)

One might use several thousands of these devices to power the main Linac of a collider

However, neither the *inexpensive* rf source nor the *very fast* modulator exist, only ideas at the moment.

The need for RF Pulse compression

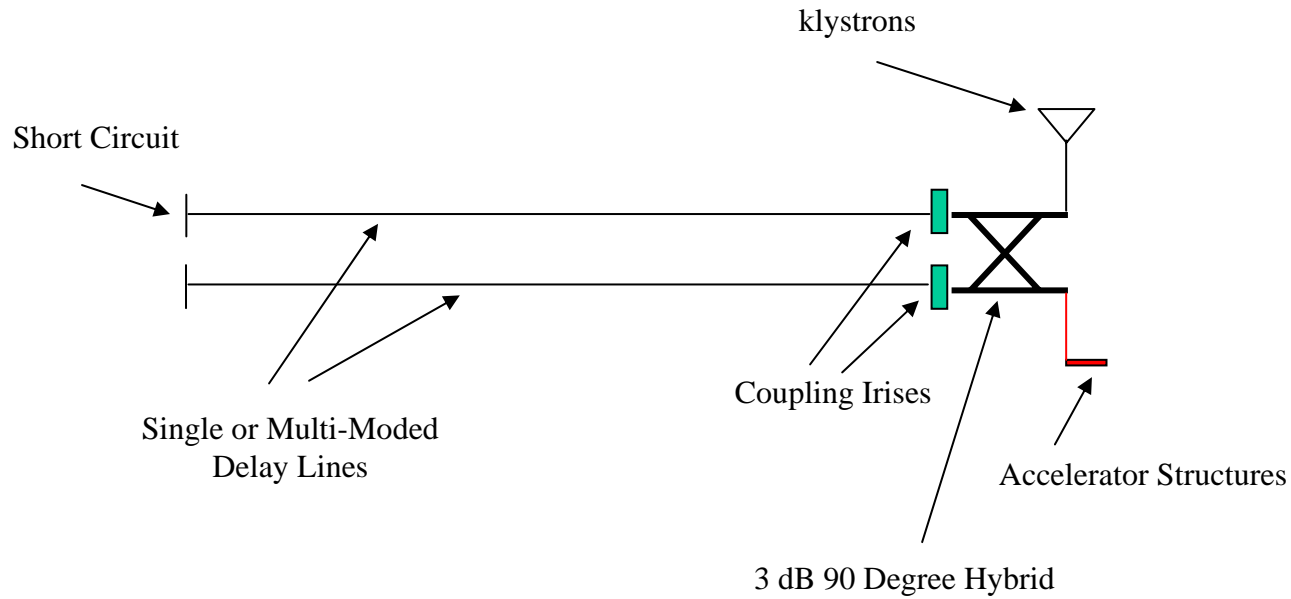

- 1- It is usually easier to build rf sources with low power and long pulse width.
- 2- Rf sources are expensive, one should get as much energy from them as possible, i.e., the longest possible pulse. One should not let an expensive rf source in an idle mode most of the time.

Hence, rf pulse compression is needed to match the long pulse low power of available rf sources such as klystrons to the high power short pulse needed for the accelerator structure.

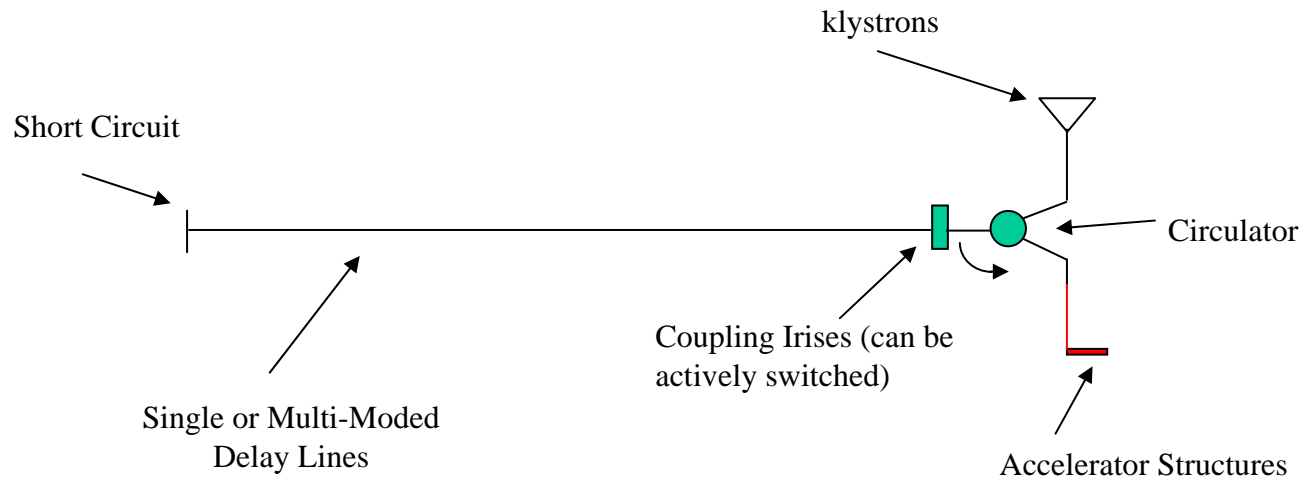

- Pulse Compression should be used with as high of a compression ratio as possible until
 - a) The cost of the compression system starts to exceed that of the klystrons and modulator
 - b) Or, the available pulse width of the klystrons is exhausted
- The cost of the main linac is directly proportional to the efficiency of the pulse compression system.

RF Pulse compression for RF Linacs and Colliders

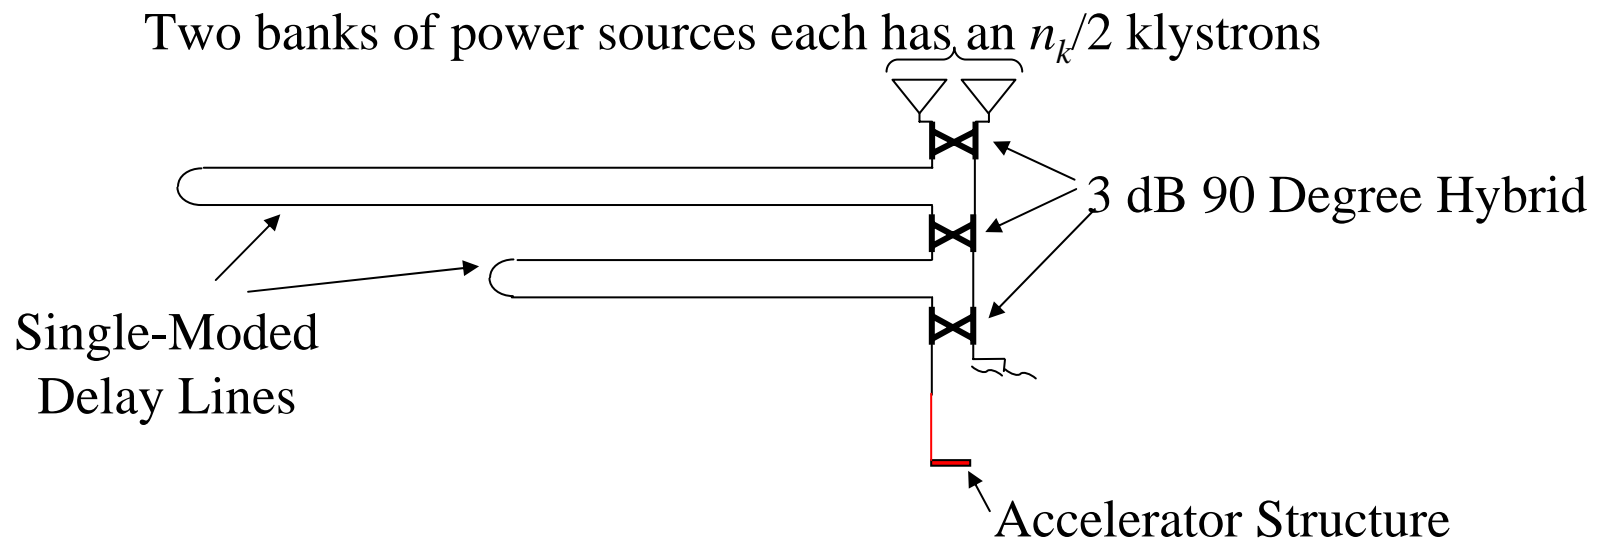

- Resonance Delay Lines (SLED-II)
- Binary Pulse Compression (BPC)
- Delay Line Distribution System (DLDS)
- Two-Stage systems, any combination of two or more of the above systems

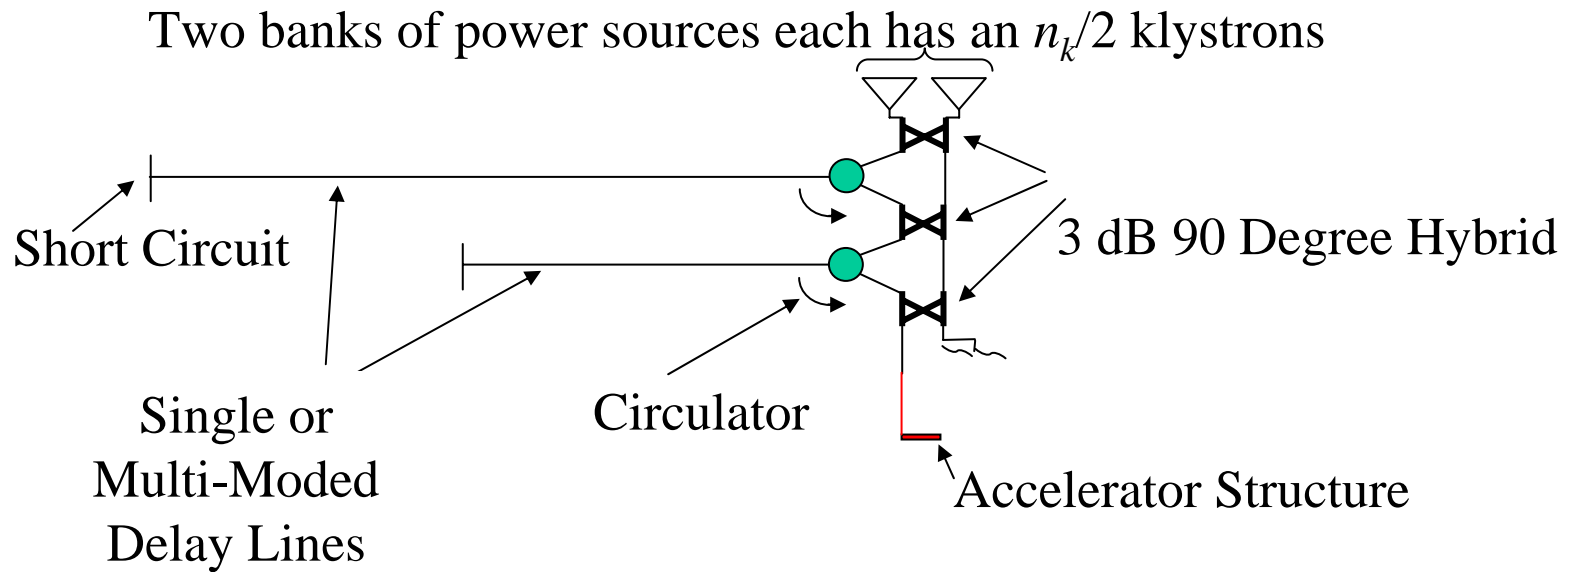

Sled-II Pulse compression system

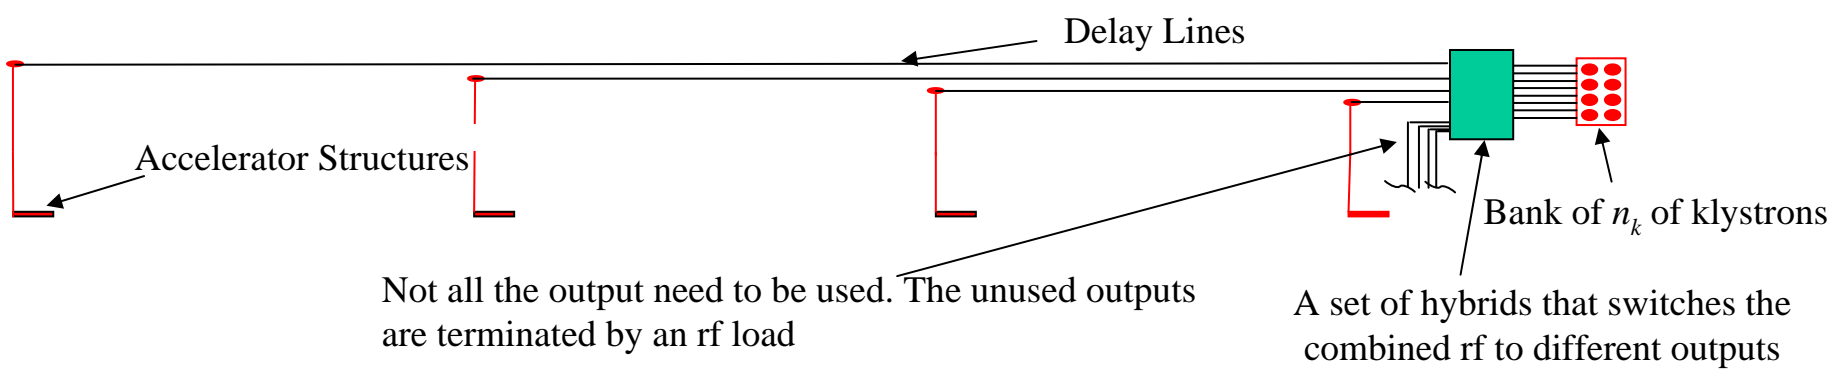

Sled-II pulse compression system with a circulator and active switches

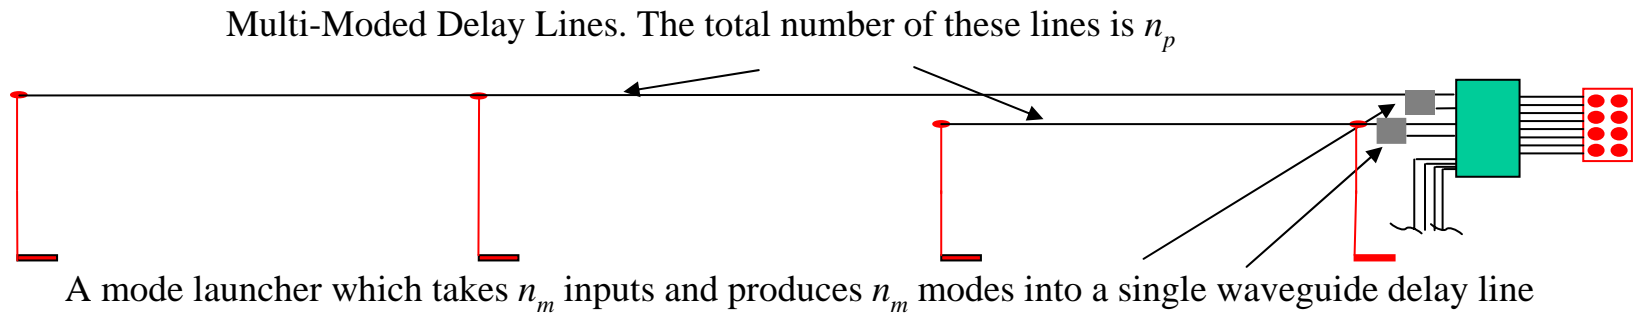

a) Single-mode Binary Pulse Compression

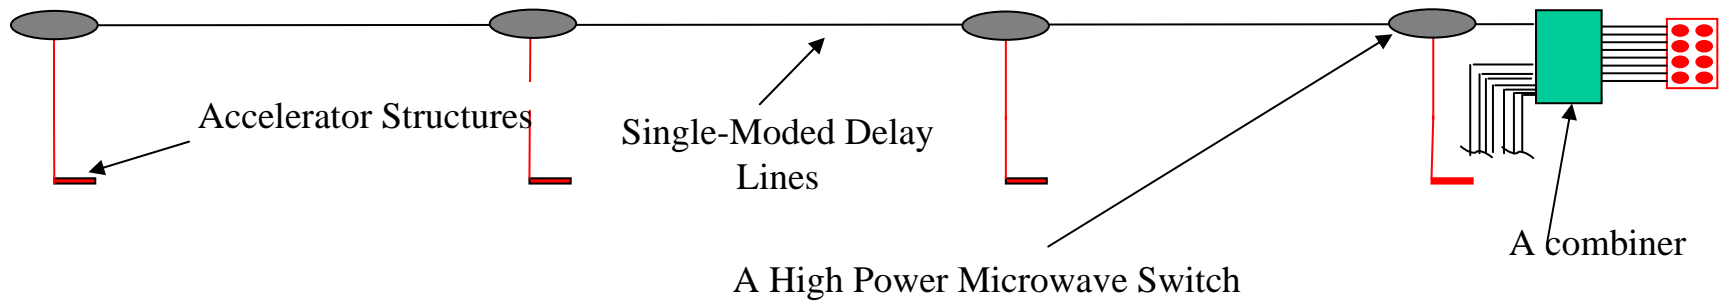

b) Binary pulse compression can have several improvements including the use of a circulator and several modes to reduce the delay line length.

a) A Unit of a Single-Moded DLDS

b) A Unit of a Multi-Moded DLDS

c) A Unit of an Active DLDS

The challenges facing most of these pulse compression system are

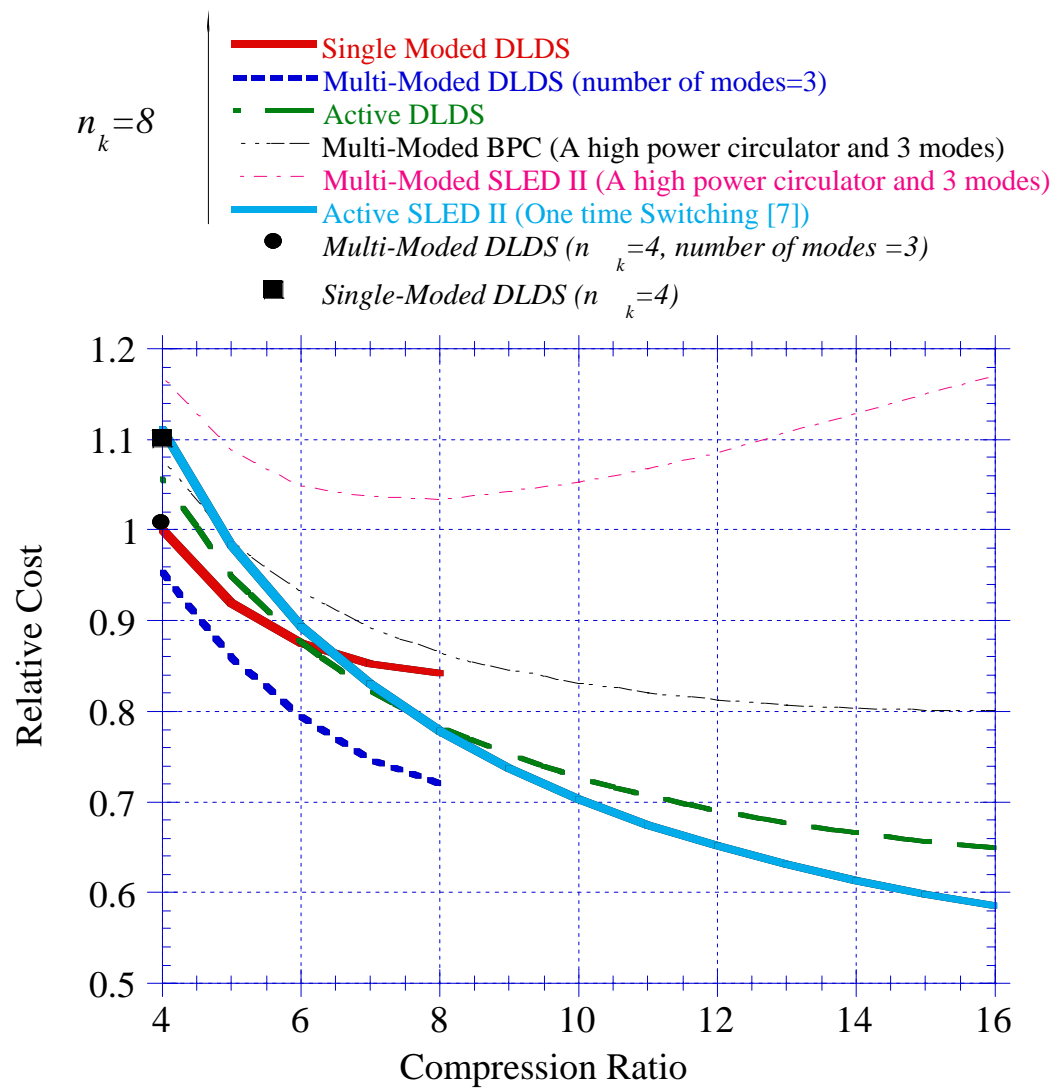

1- Compactness, how to produce a storage system which is relatively compact

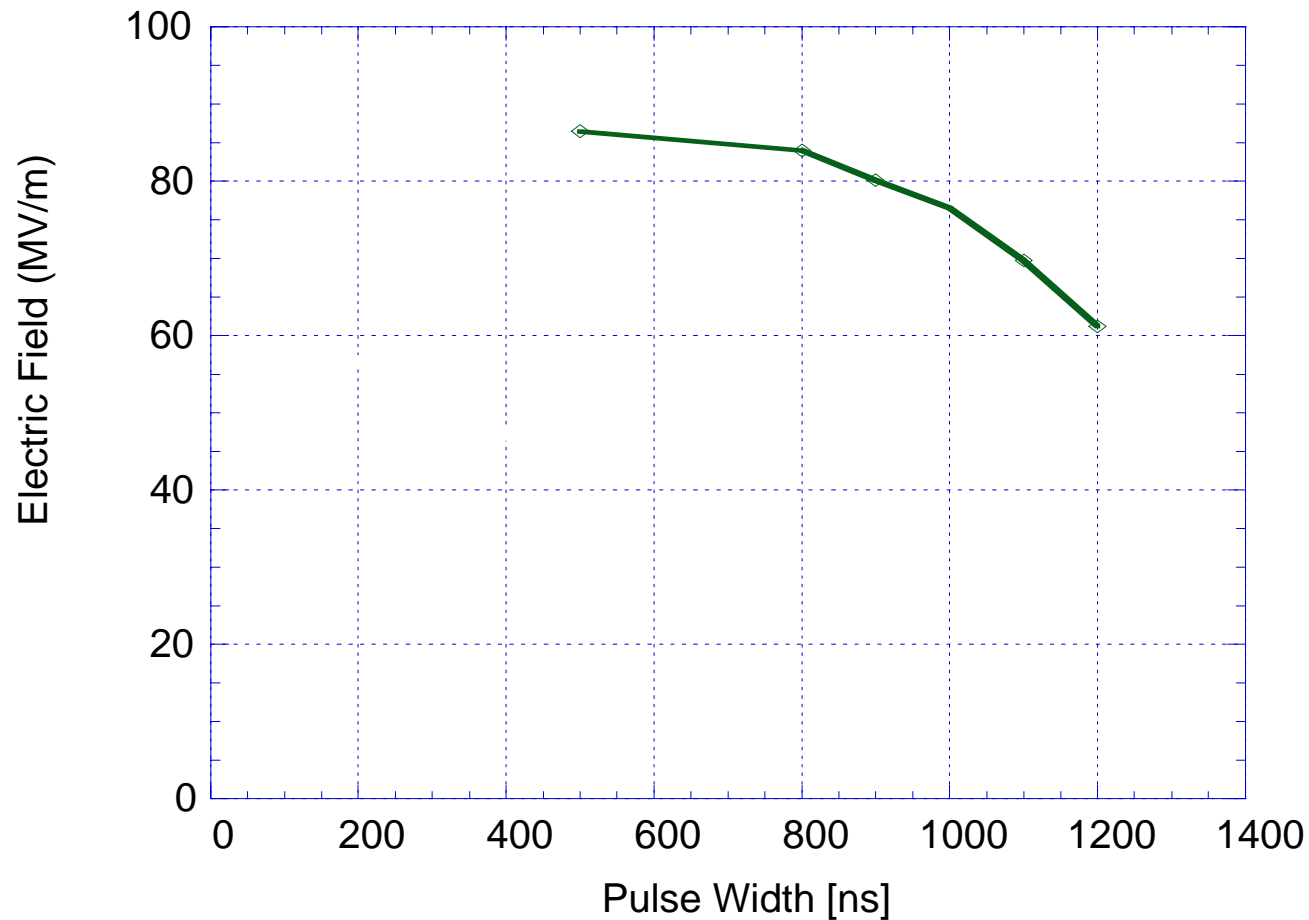

2- Efficiency, for the resonant delay lines, efficiency could be boosted by an **rf switch**.

3- Most of these systems could have a more compact topology if one have, a nonreciprocal RF device (**circulator**), or a **switch**.

Compactness

- A waveguide near cutoff, hence, a low group velocity. One can use a higher order mode to reduce the losses. A bad idea, dispersion will destroy the pulse shape at a group velocity less than 4.
- Loaded waveguide (slow wave structure). A bad idea because of dispersion and losses.
- Multimoded Waveguide, the only good idea with no drawbacks. We are using highly overmoded waveguide systems no matter what, using an extra mode, or two, or four, .. Is a bonus.

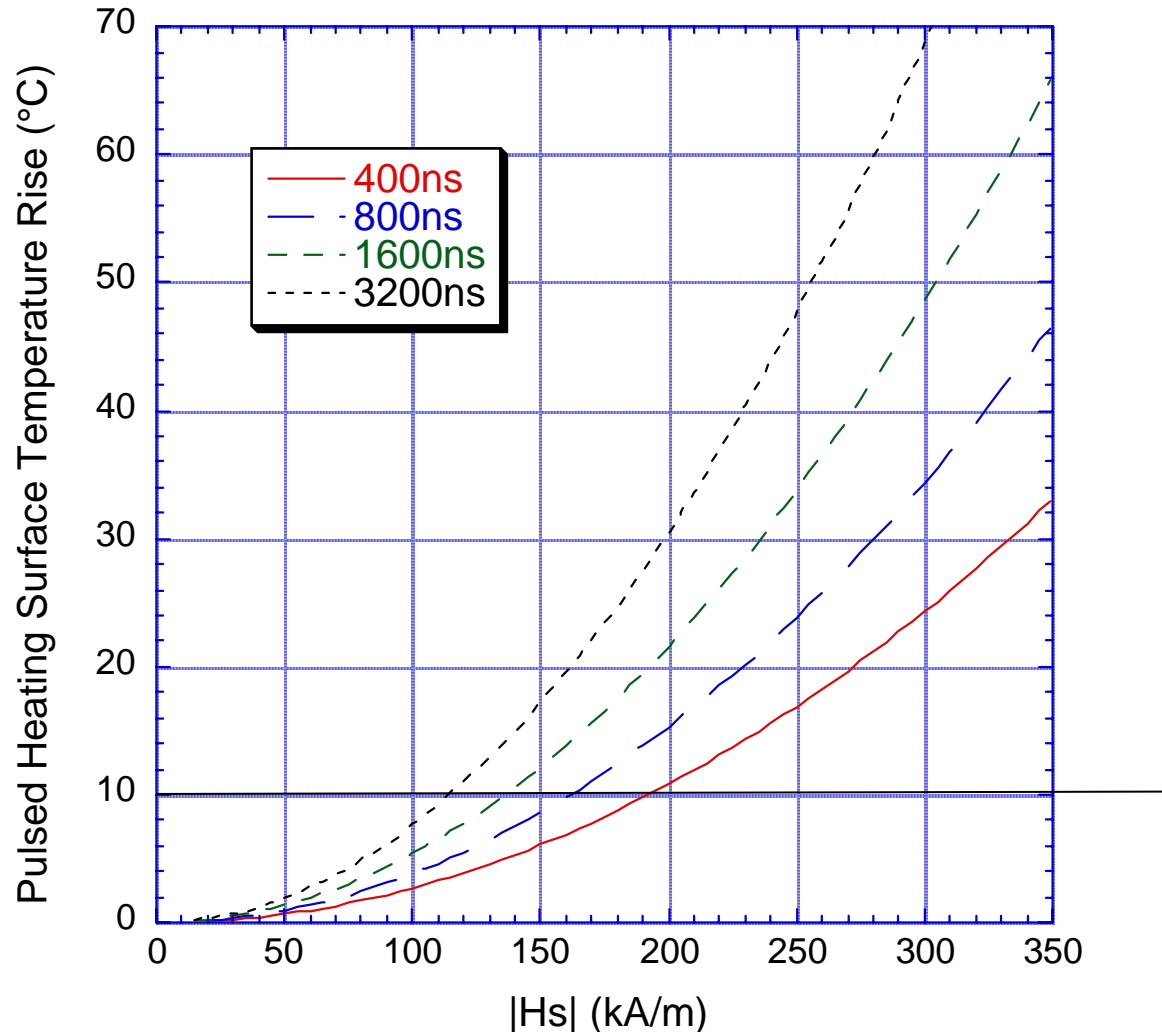

Electric Field breakdown strength in a 16% Group velocity copper waveguide at 11.424 GHz

Dual-Moded Rectangular ↔ Circular

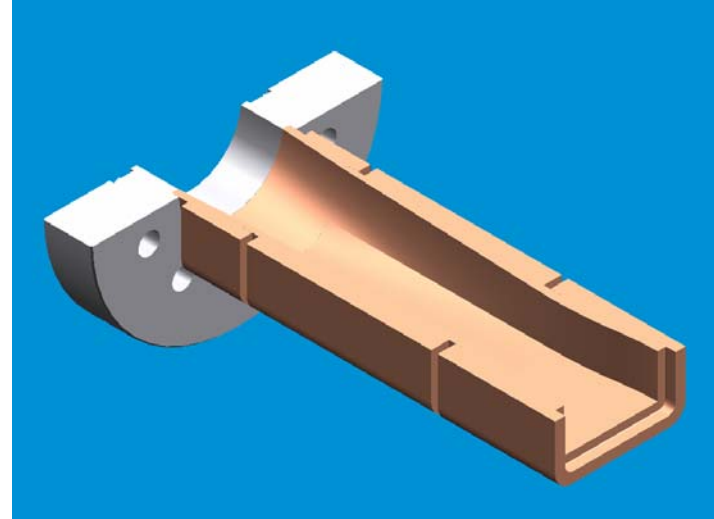

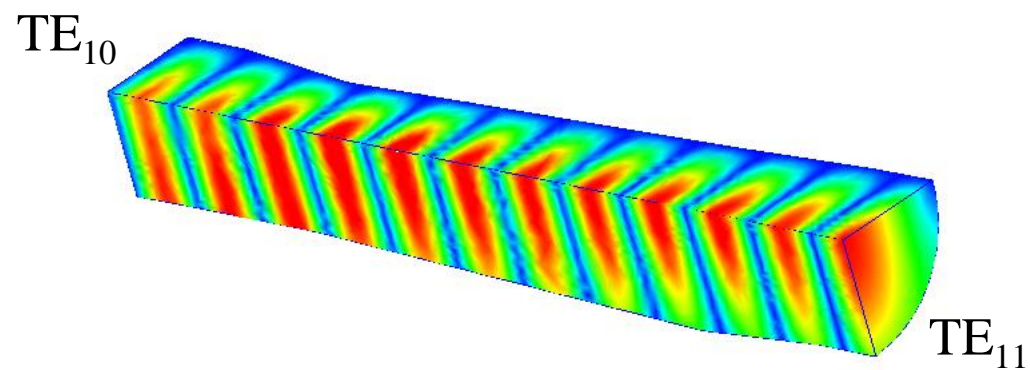

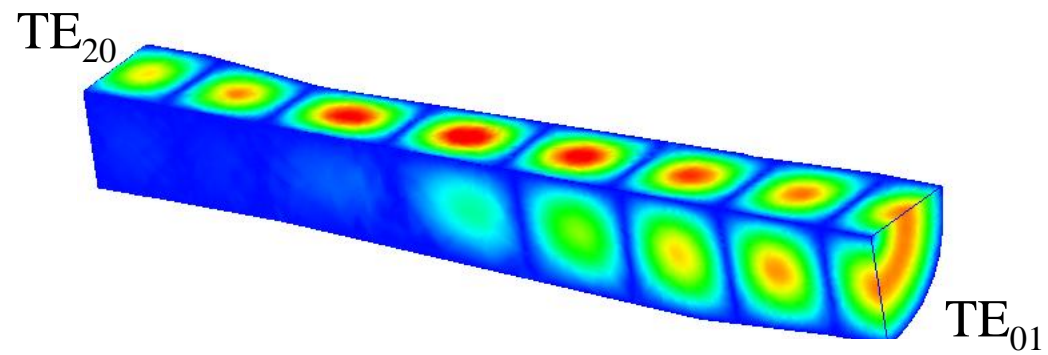

Converter/Tapers

Taper Geometry (Operating Frequency=11.424 GHz)

Dualmode Rectangular-to-Circular Taper

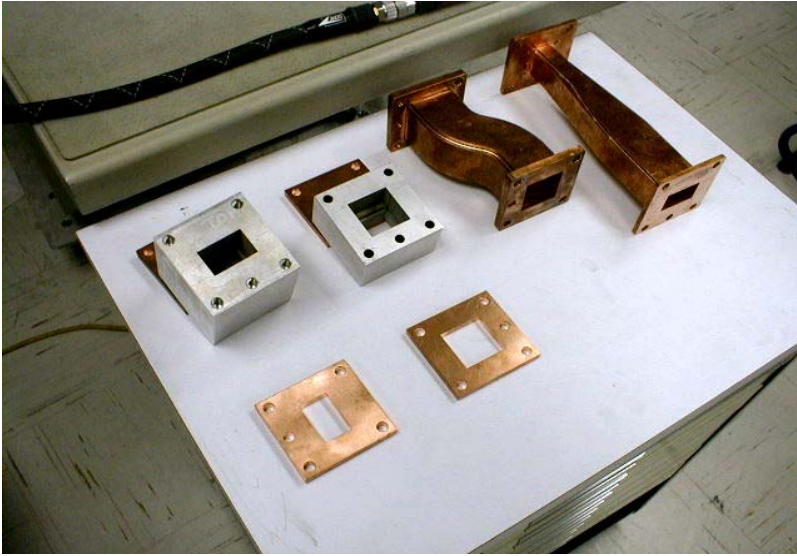

Instrumental components for cold testing of multimode components:

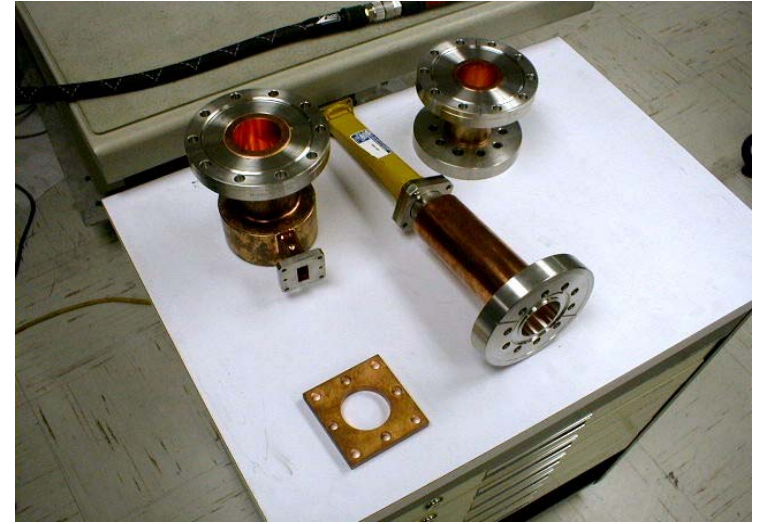

1. TE_{11} Mode launcher
2. TE_{01} Mode launcher
3. Width taper
4. Height taper
5. Small waveguide sections with different lengths at all waveguide cross sections

We followed a strict methodology of designing these instruments. They had to be simulated with at least three different codes and have a performance that is much better than any component that we have. Of course we can only do that because there is no restrictions on field levels.

Cold Test Components/Calibration Standards

p1sled2

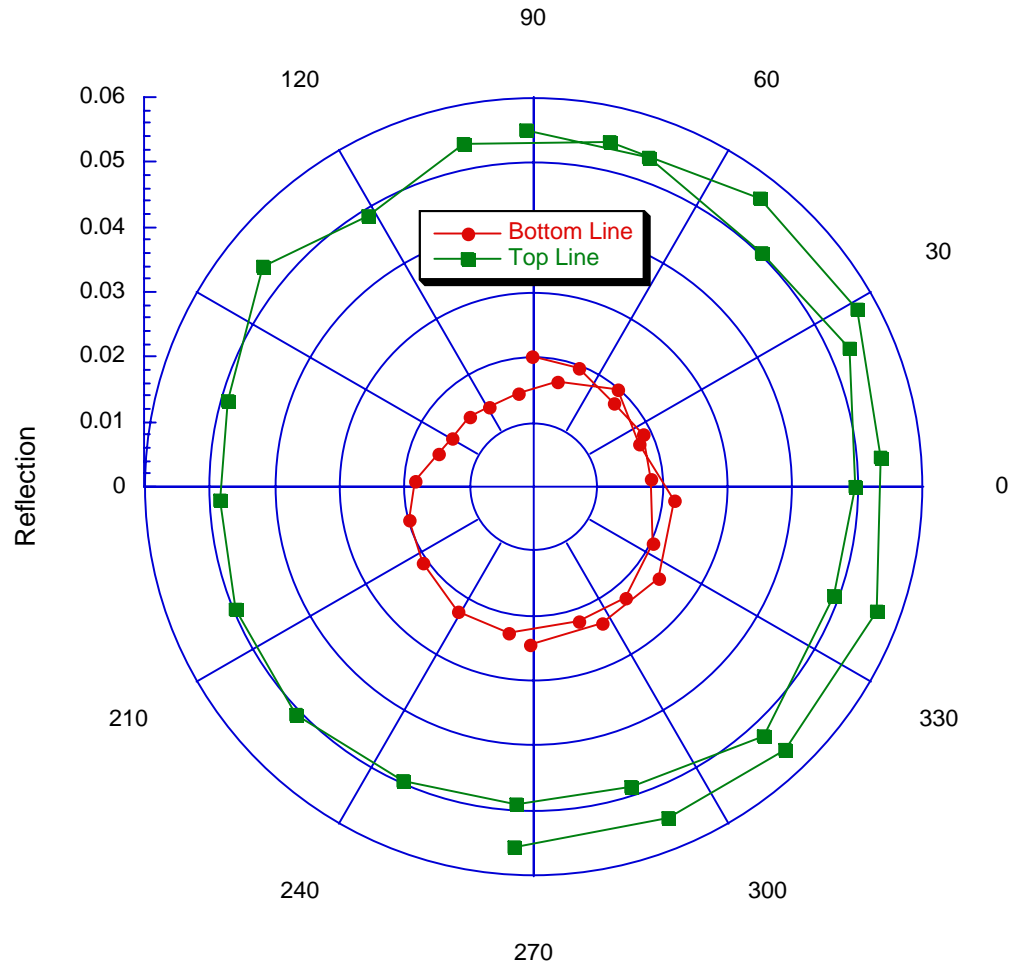

Small mid-time-bin steps seen
(mode impurity).

Spurious reflection after first round trip (irises removed)

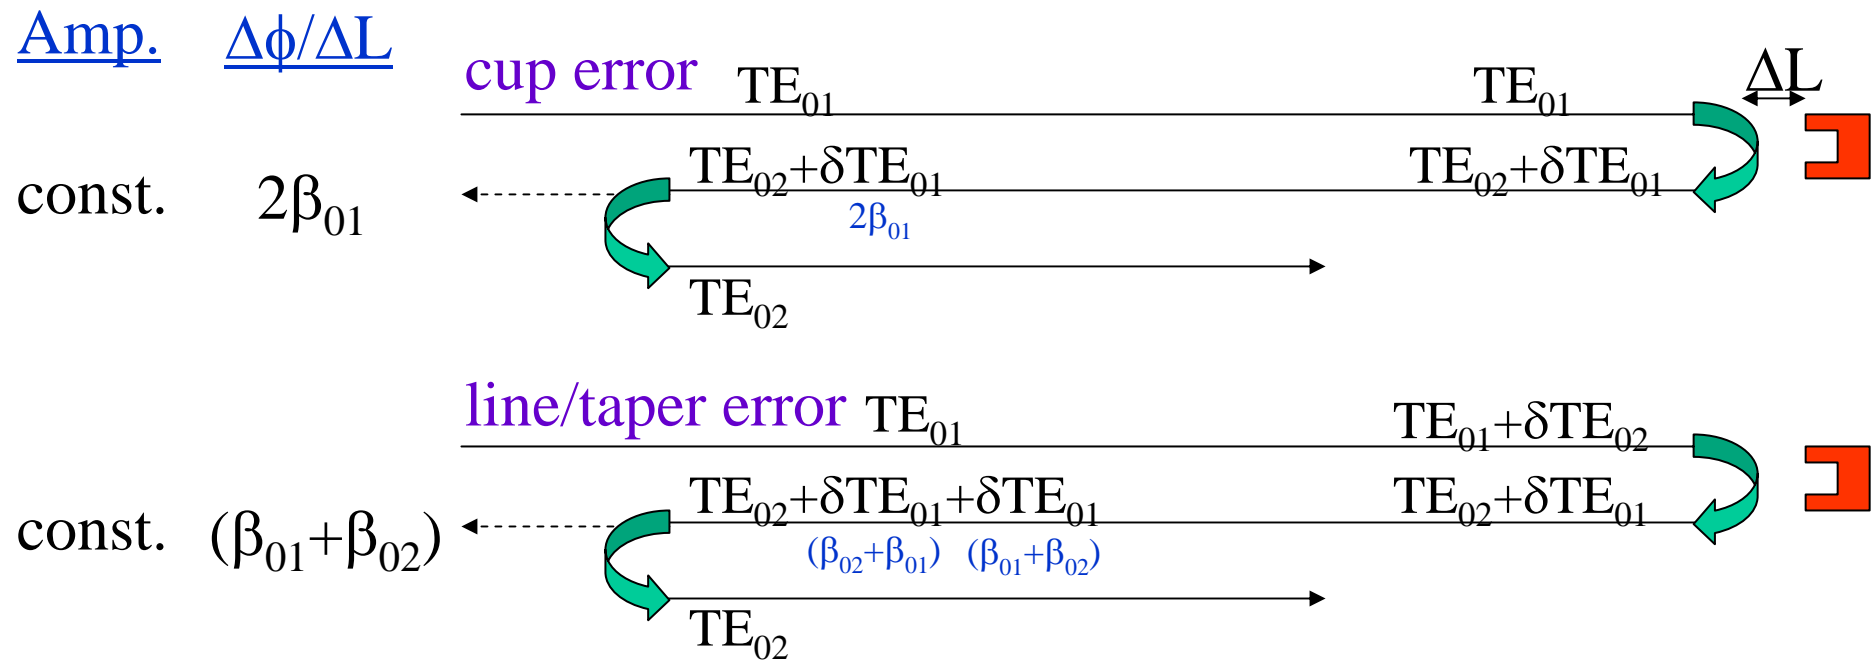

Amplitude oscillation due to interference with slight wrap-around mode launcher mismatch (~ -48 dB).

TE01 mode contamination

bottom line: ~ -34 dB

top line: ~ -26 dB

The wavelengths for these phase oscillations are 14.2 mm and 16.1 mm, respectively.

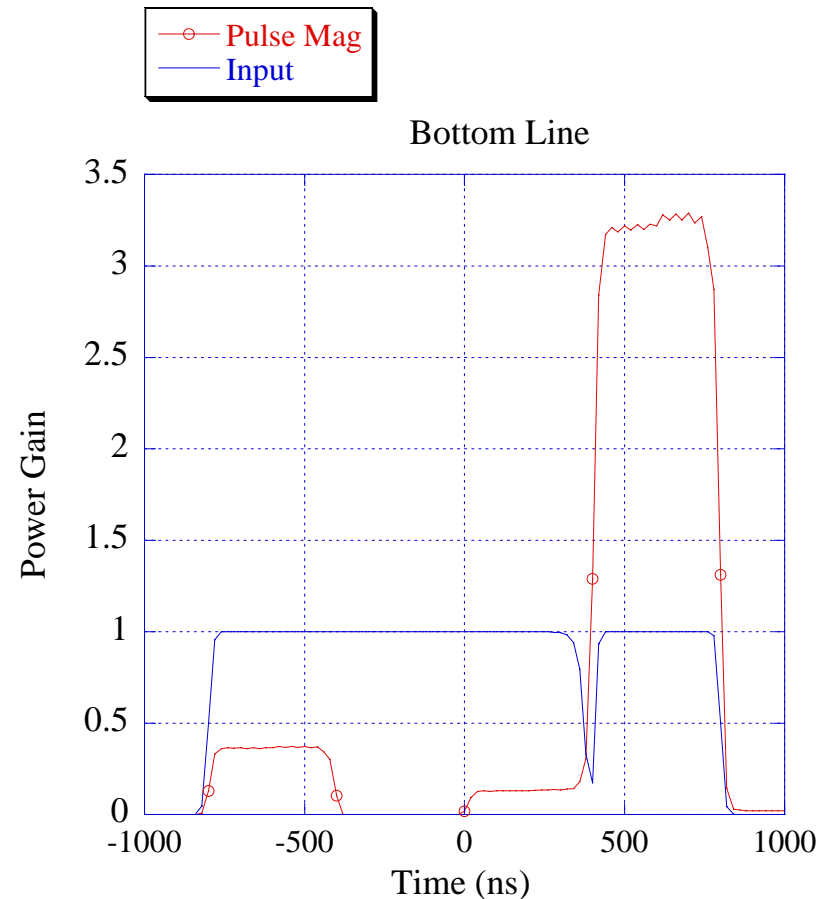

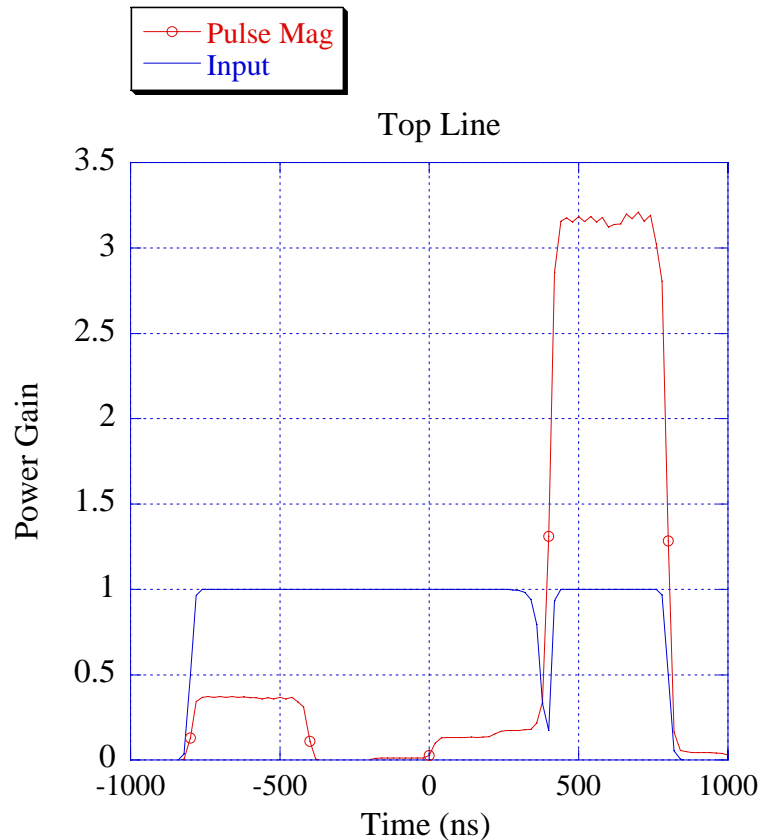

Measurements show a phase cycle over ~ 16 mm, indicating mode contamination predominantly from the delay lines and tapers.

Slight amplitude oscillations reveal a very small fixed mismatch in wrap-around mode launcher.

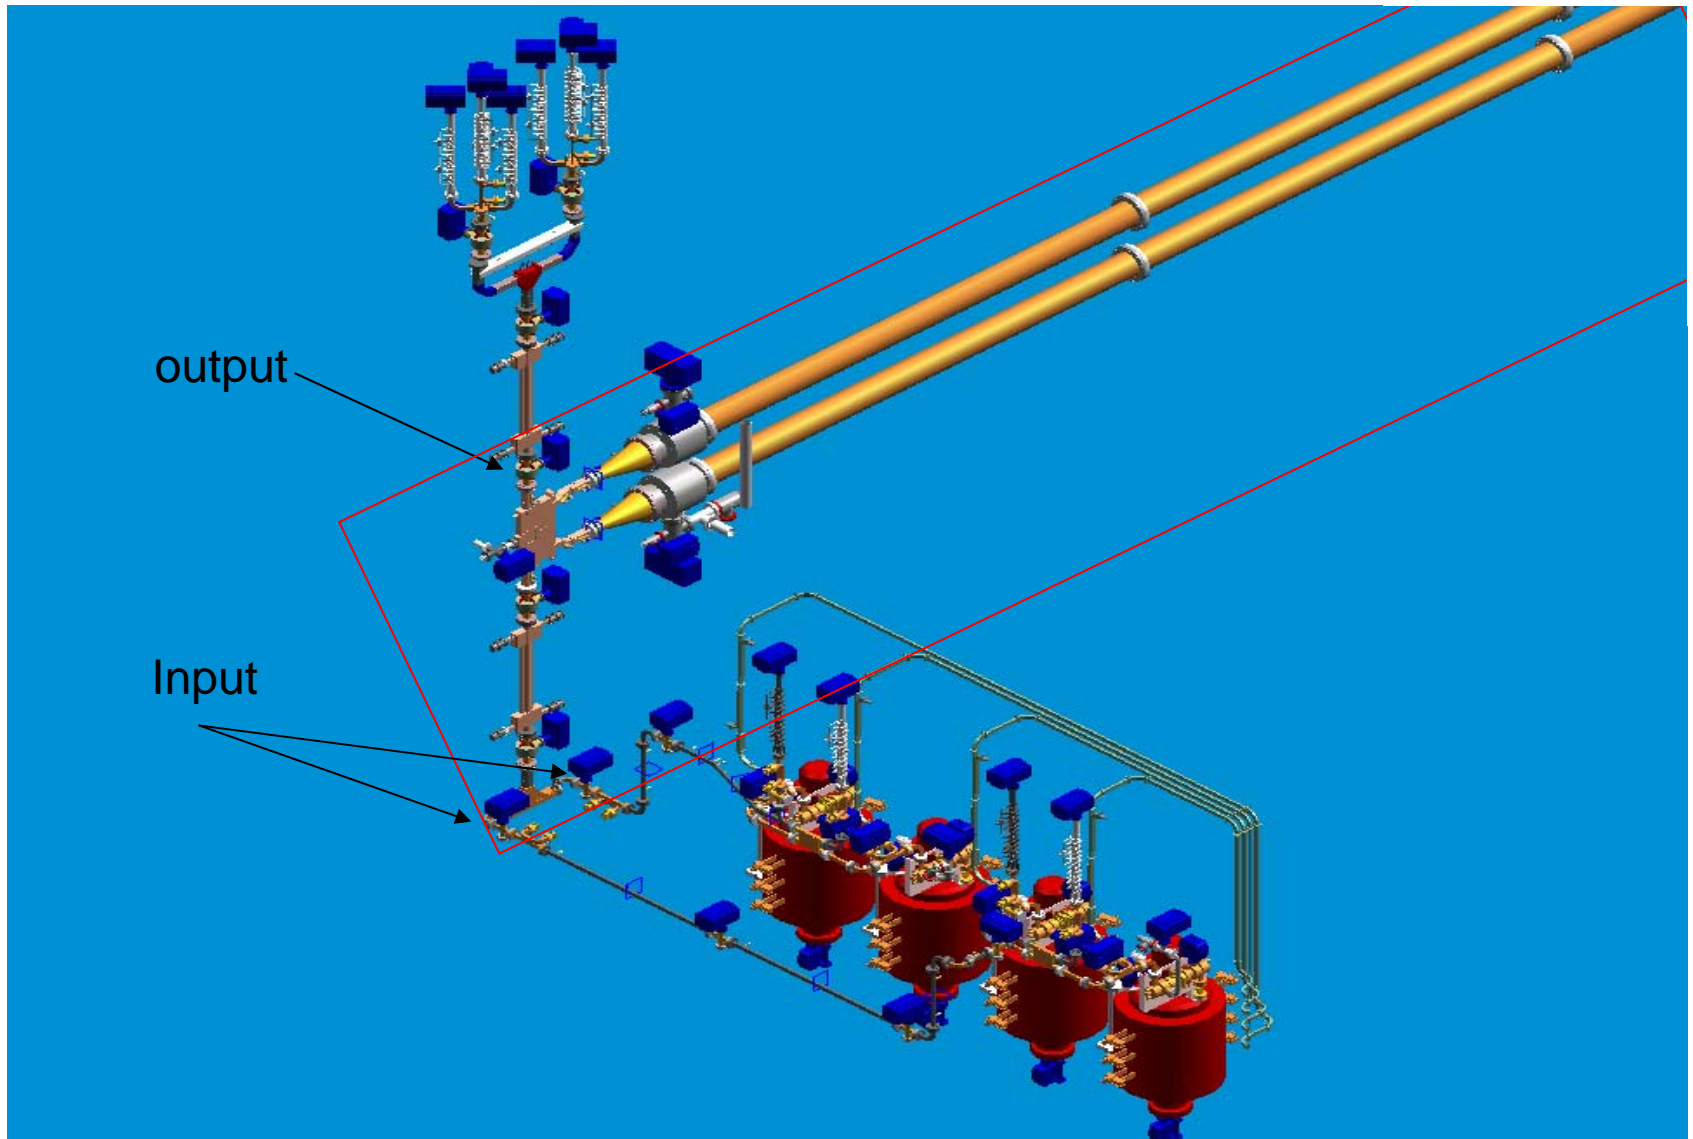

Non-periodic amplitude change can be attributed to longer range beating between a small cup error contamination and that from the lines/tapers (60.3 mm).

Problem Fixed by:

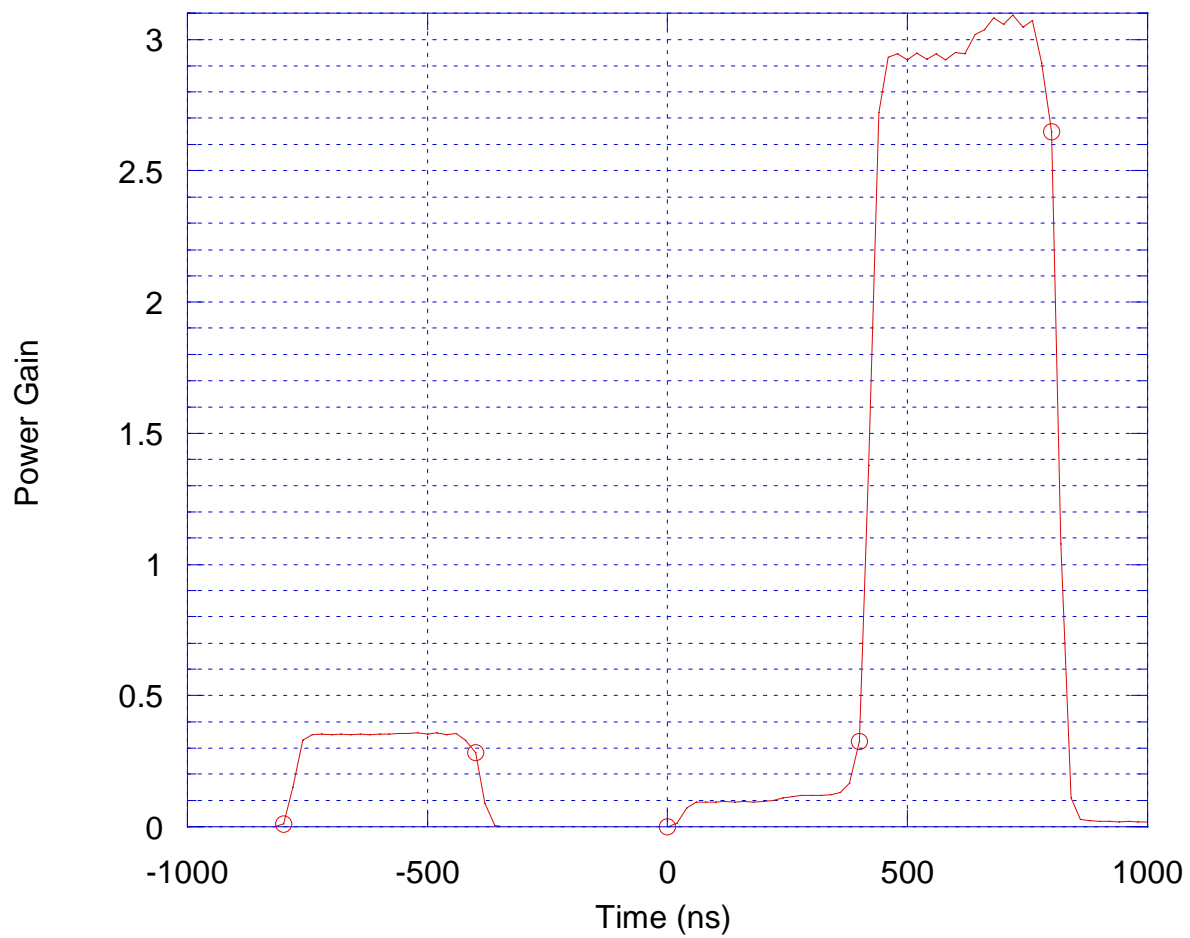

- Permutations of tapers
- Adjusting iris distance
- Choosing good resonant position for tuning plunger (3 within range of motion).

The cell is not matched enough. We can match two cell or structure of several cells by placing the cells at right distance from each to other. But to get more smooth passband is better to match each cell by iris.

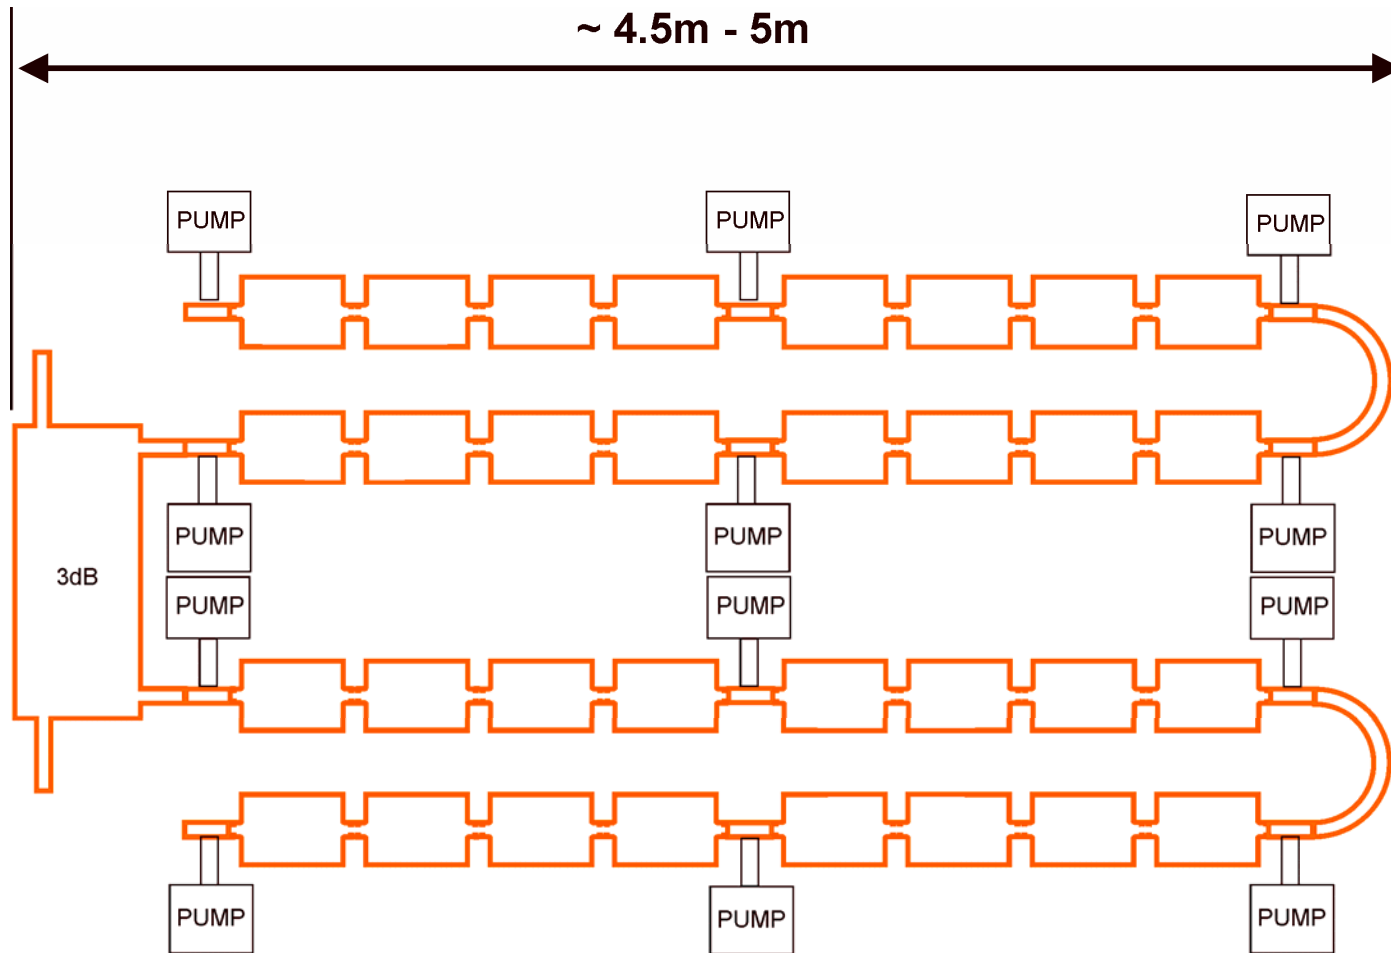

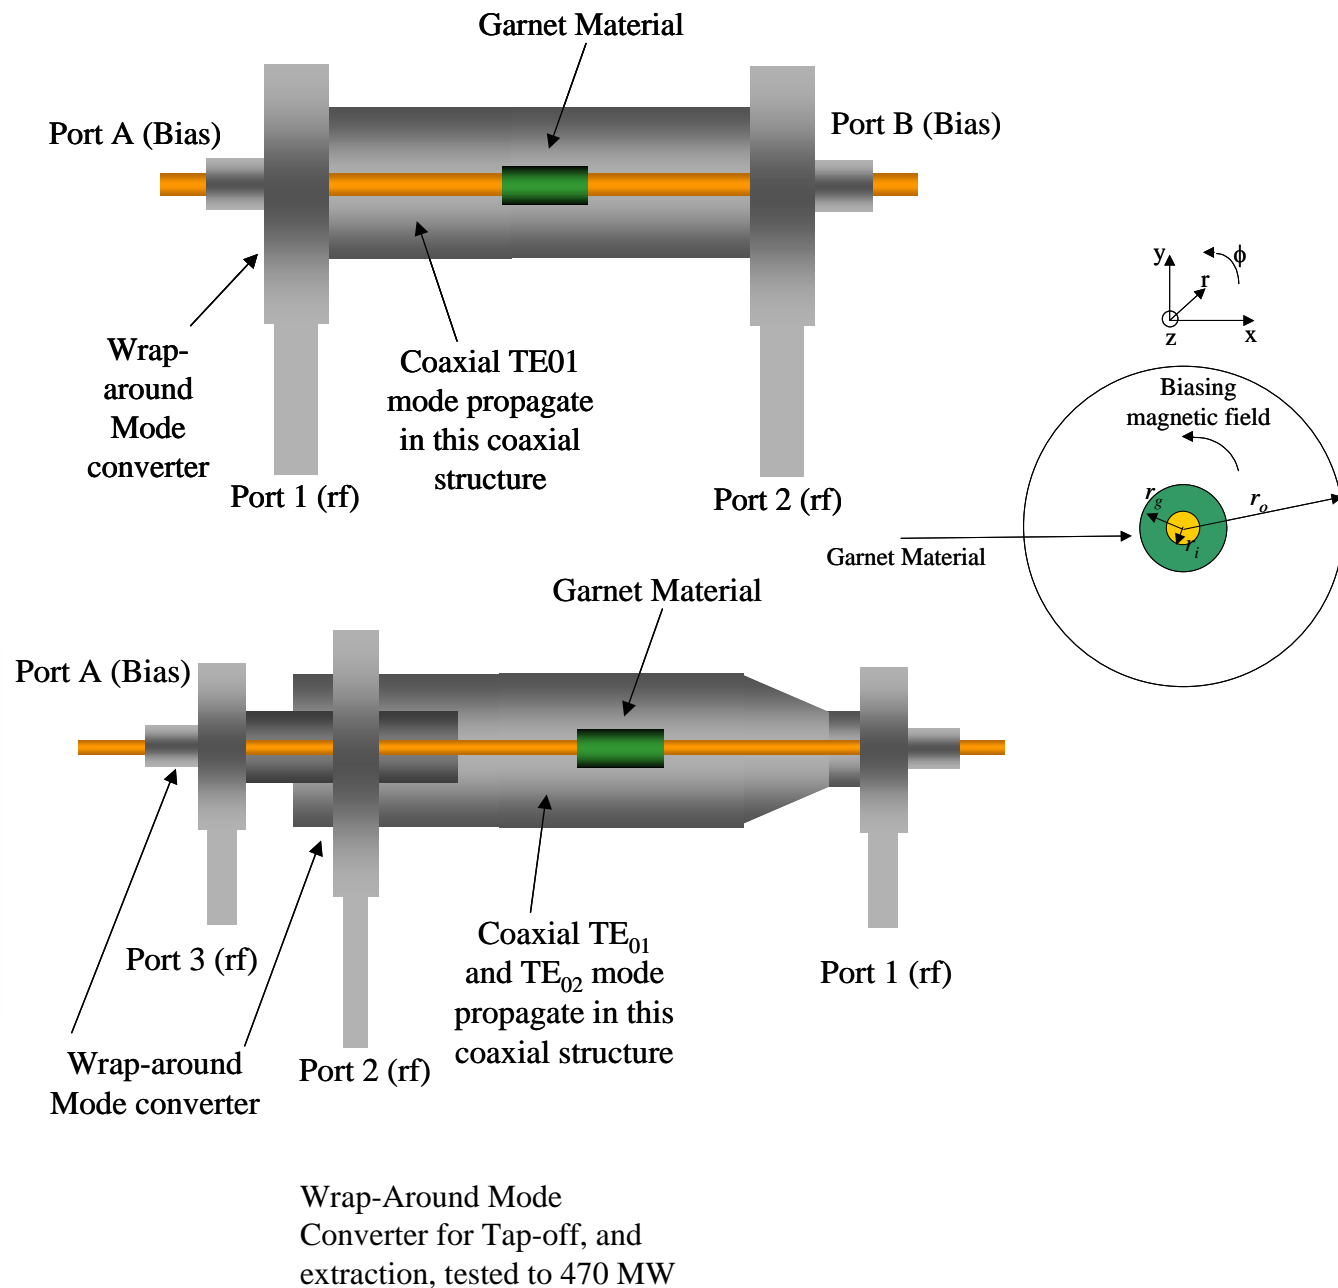

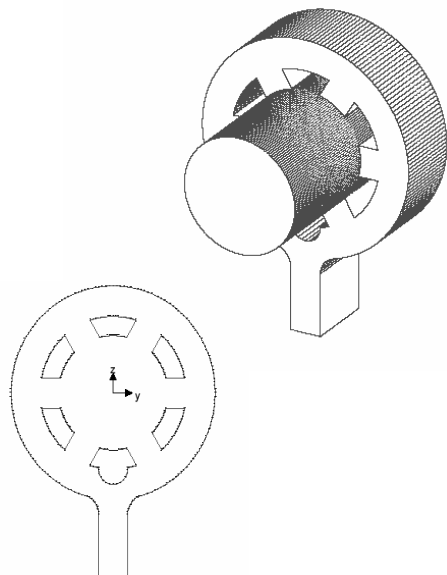

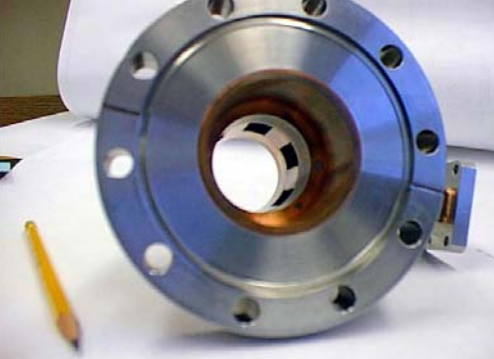

Geometry of cell with matching irises.

Passband of single cell

Total length of SLED-II can be not more than 5m

Conclusion:

- We have introduced a fully dual mode rf system
- We have shown design and experimental data for over moded components that propagate two modes at the same time. These components perform all possible functions found in single moded rf systems
- At the operating frequency of 11.424 GHz, the peak electric field is ~ 49 MV/m (400 ns) and the peak Magnetic field is ~ 0.17 MA/m (400 ns). This was demonstrated to be low enough for a reliable high power operation of the system.

Conclusion:

- We have introduced a fully dual mode rf system
- We have shown design and experimental data for over moded components that propagate two modes at the same time. These components perform all possible functions found in single moded rf systems
- At the operating frequency of 11.424 GHz, the peak electric field is ~ 49 MV/m (400 ns) and the peak Magnetic field is ~ 0.17 MA/m (400 ns). This should be low enough for a reliable high power operation of the system (remain to be seen)
- We have invented several new measurement techniques and instrumental components needed for characterizing dual moded rf systems.
